Fix the yellow underline on import hatanaka

Quick guide · Pylance · Python environments · VS Code

If the script runs successfully but **hatanaka** has a yellow underline, VS Code may be analyzing the file with a different Python interpreter from the one used to run it.

1 Check what the warning actually says

Hover over **hatanaka** and wait for the message. If the warning looks like the following, proceed with these steps:

```
Import "hatanaka" could not be resolved
Pylance(reportMissingImports)
```

2 Select the correct Python interpreter

In VS Code:

- Press **Ctrl + Shift + P**.
- Type **Python: Select Interpreter**.
- Select the Python environment you use to run the script.

If you use **Conda**, select the same environment that is active in your terminal.

3 Check where Hatanaka is installed

Open the integrated terminal and run:

```
python -m pip show hatanaka
```

If it is installed, you should see something similar to:

```
Name: hatanaka
Version: ...
Location: C:\...\site-packages
```

Also check which interpreter runs your code:

```
python -c "import sys; print(sys.executable)"
```

The displayed path should match the interpreter selected in VS Code.

If the library is not installed in that environment, run:

```
python -m pip install hatanaka
```

4 Restart VS Code analysis

If the interpreter is correct but the warning remains:

- Press **Ctrl + Shift + P**.
- Type **Developer: Reload Window**.
- Press **Enter** to reload the window.

If the warning persists. Read the exact message displayed when you hover over the import. For example, **reportMissingModuleSource** calls for a different diagnosis. It is better to fix the environment than disable Pylance warnings.
